1.0 Introduction

This report summarizes the analysis carried out to define hydraulic backwater flood elevations and develop digital flood line inundation mapping for Wanatango Falls, located on the Frederick House River.

This report will summarize a generalized overall methodology used in the construction of the HEC-RAS models for The Wanatango Falls Site and provide commentary on key project requirements and assumptions used within the modelling. The terms “flood” and “inundation” have been used regularly in this report and have been intended to be understood in the same context.

2.0 Project Purpose and Scope

The purpose of this report is to develop a steady state and un-steady state hydraulic model using the latest HEC-RAS 4.1.0 software and provide flood inundation mapping for Wanatango Falls. The hydraulic model will replicate a number of flow scenarios during existing conditions as well as flow conditions that will be anticipated after construction of a proposed hydroelectric dam.

A total of six flow profiles have been selected to be simulated using the steady state model, outlined in **Table 1** below.

Table 1: Simulated Flow Profiles

Flow Description	Flow	Existing Conditions	Proposed Conditions
Calibration Flow	2.0	X	
Validation Flow	5.0	X	
Long Term Average Flow (LTAF)	33.2	X	X
*High Water Mark Flow (HWM)	55-160	X	
1:2 Year Flood Flow	188.7	X	X
1:100 Year Flood Flow	425.20	X	X

The HWM flow for Wanatango Falls has not been provided but rather will be determined through the modeling. The Wanatango Falls Site is remote and there are no structures or Town(s) in close proximity to the site where a High Water Mark can be confirmed. Commentary outlining the computational procedure has been outlined in **Section 4.3.2** below.

Headpond Inundation Mapping Hydraulic Report
Frederick House River-Wanatango Falls
June 29, 2011

The un-steady state hydraulic model has been developed to represent operating conditions associated with the proposed dam. This modeling scenario will be further discussed in **Section 5.0** below.

The HEC-RAS model iterations were completed to calibrate to a desired vertical tolerance of $\pm 0.1\text{m}$. Given the absence of low flow geometry in key areas of each reach, a desired vertical tolerance of 0.1m may not be achievable. Key areas would include but are not limited to sections of turbulent flow through rapids, riffle crests, area's experiencing split flow scenarios, etc. The use of survey data, aerial photography, site photos, measured flows and available mapping has bee used to calibrate each model. Please refer to **Section 4.1** for additional details on the calibration procedure.

The hydraulic model will be further validated using pro-rated hydrometric data from the Water Survey of Canada and water surface elevation data extracted from LIDAR mapping. Further commentary has been provided in **Section 4.2** outlining the validation procedure.

3.0 Background Information

The preparation of this report and the hydraulic modeling outlined in this report draws information from several sources. These sources include LIDAR Reports/Mapping, conceptual drawings, hydrology reports, survey/bathymetry data, measured flow data and Water Survey of Canada Hydrometric data, etc. This background information has been referenced accordingly within this report.

4.0 Steady State Hydraulic Modeling

Survey and bathymetry data has been provided for The Wanatango Falls Site and provided by BPR Engineeringⁱ. A total of seven survey sections (Section ID -4 to 3) has been provided for Wanatango Falls. These survey sections have been located upstream, downstream and in the close vicinity of the proposed structure. Bathymetry data has also been provided key non-turbulent areas upstream and downstream of the proposed structure.

Beyond the limits of survey and bathymetry data, LIDAR mapping was provided by Xeneca Power (Xeneca) and obtained by a flight over the project site on June 25, 2009 by Terrapoint^{vii}. The mapping extends approximately 1.9km downstream to 10.0km upstream of the proposed structure.

Steady state modeling for this report has been completed using cross sectional survey/bathymetry data as well as using available LIDAR data. The location and alignment of the survey sections have been maintained in the modeling. Additional cross

sections have been cut and added to the model in key locations throughout each reach that may have an impact on the flood elevations. These locations include but are not limited to river profile changes, expansion/contraction of the anticipated floodplain, areas in close proximity to the proposed structure, etc.

4.1 Calibration Procedure

The calibration of the existing condition HEC-RAS modeling has been completed using a four step iteration process. The iteration process has been started with minimal data and further moving to a more complex model. Applicable manning's coefficients for the main channel section and overbanks have been selected by observing site photos and aerial photography for each site. Generally, a manning's $n=0.10$ has been applied to the overbank areas for thick dense wooded vegetation. A manning's $n=0.03-0.035$ has been applied to the main channel and corresponds to the USGS Verified Roughness Characteristics of Natural Channels^V. These coefficients correspond to values outlined in Table 3-1 of the HEC-RAS Hydraulic Reference Manual^{IV}.

For the calibration procedures, a known survey water elevation of 248.65m was used as downstream boundary condition. A measured flow of $2.0\text{m}^3/\text{s}$ was used for the calibration procedure. Computed HEC-RAS water surface elevations were then compared with surveyed water surface elevations. Measured flows and survey data have been provided by BPR Engineering^I.

Firstly, a simplistic model consisting of only survey cross sections within the model was created. In general, computed water surface elevations at the downstream survey cross sections was observed to be within the required 0.1m vertical tolerance with noticeable differences outside the tolerance of 0.1m moving upstream. These results can be attributed to the normal flow conditions experienced at the downstream limits of the site and absence of required data in key areas of the model required to produce the required water surface elevations moving towards the upstream limits of the sites. Results of this first iteration are summarized on within **Appendix A** on **Figure 1**- with the column heading **1-Water Elev(m)**.

Secondly, building on the first iteration, additional cross sections were added to the model. These additional cross sections utilized the available LIDAR data and survey bathymetry data in the model. Again, computed HEC-RAS water surface elevations were then compared with surveyed water surface elevations. Generally the vertical separation between the computed water elevations and surveyed water elevations improved but yet were still outside the required tolerance. Results from the second iteration are summarized within **Appendix A** on **Figure 1**- with the column heading **2-Water Elev(m)**.

Headpond Inundation Mapping Hydraulic Report
Frederick House River-Wanatango Falls
June 29, 2011

Thirdly, after observing the results from the second iteration, additional cross sections were again added to the model. These additional cross sections were cut using LIDAR data only and added in key control areas of the reach. Again, computed HEC-RAS water surface elevations were then compared with surveyed water surface elevations.

Generally the computed water surface elevations were observed to be higher than the surveyed water elevations. This can be attributed the absence of low flow geometry within the newly created sections. Results from the third iteration are summarized within Appendix A on **Figure 1**- with the column heading **3-Water Elev(m)**.

Finally, maintaining the same quantity and locations of cross sections of the third iteration, low flow geometry was added to LIDAR cross sections below the LIDAR water surface elevation. The low flow geometry has been interpolated from surveyed/bathymetry cross sections in close proximity to the LIDAR section. The low flow geometry has been adjusted to both vertically and horizontally to fit the newly added LIDAR Sections. Again, computed HEC-RAS water surface elevations were then compared with surveyed water surface elevations. The depth of the low flow geometry at each cross section was further adjusted where applicable to produce computed results within the desired vertical tolerance. Results from the fourth iteration are summarized within **Appendix A** on **Figure 1**- with the column heading **4-Water Elev(m)**.

Calibration and validation results for each site have been provided on **Figure 1 of Appendix A**

The calibration result comparison tables illustrated on **Figure 1 in Appendix A** have been provided at survey cross section locations only. These locations have been selected for comparison purposes only as there are two known data sets (measured flow and survey low geometry) in which computed water surface elevations and surveyed water surface elevations may be accurately compared. The calibration water surface elevations for Wanatango Falls has been modeled to within 0.55m of the surveyed water elevations. This vertical range in water surface elevations is outside the desired vertical tolerance of 0.1m, however, commentary supporting the calibration results has been provided in **Section 4.2** below.

4.2 Validation Procedure

The validation procedure for Wanatango Falls has built on the calibrated model results as outlined in **Section 4.1.1** above.

LIDAR mapping was obtained by a flight over the project site on June 25, 2009 by Terrapoint ⁱⁱⁱ, The Wanatango Falls site is located downstream of the Frederick House Dam. Accordingly, a flow of 0m³/s has observed on June 25, 2009 at the Frederick House Dam. Comparatively, the flow from the Frederick House Dam was also measured

Headpond Inundation Mapping Hydraulic Report
Frederick House River-Wanatango Falls
June 29, 2011

to be 0m³/s on October 16, 2010, the date at which a flow of 2.0m³/s was measured at the Wanatango Falls site by BPR Engineering¹. To account for sheet flow and runoff from tributaries located between the Wanatango Falls site and the Frederick House Dam, an arbitrary flow of 5m³/s was used for the validation procedure.

For the validation procedure, a known survey water elevation of 249.50m was used as downstream boundary condition. Using the LIDAR water surface elevations and newly acquired validation flow, the computed HEC-RAS water surface elevations were then compared with LIDAR water surface elevations throughout the model. Generally, the vertical elevation differences range from 0±0.3m depending on location within the reach.

Validation results have been generally summarized within **Appendix A** on **Figure 1** with the column heading **5-Water Elev(m)**.

4.3 Construction of the Full Reach Model

The calibration procedure and validation procedure as outlined in **Sections 4.4.1 and 4.1.2** outlined above was initially confined to the limits of the survey cross sections. Generally, the surveyed cross sections have been spaced at regular intervals of 200-300m, with one cross section located in the close vicinity of the proposed dam and three or four cross sections located upstream and downstream of the dam respectively. This would produce a total short reach length of approximately 1.6km. Anticipating a requirement to define a tailwater condition applicable for a number of flow scenarios and also a requirement to compare flood elevations (existing vs. proposed) in the head pond area of the reach, the HEC-RAS model was further extended downstream and upstream to the limits of the LIDAR mapping.

Additional cross sections have been added to the limits of the mapping in a similar format as outlined in **Section 4.1**. Generally, the limits of the mapping have produced a total modeled reach length of 12.0km.

4.3.1 Boundary Conditions

The steady state flow conditions associated with the steady state modeling was completed using a mixed flow computation procedure. The mixed flow regime requires boundary conditions to be defined at the upstream and downstream limits of the site and allows for computations of subcritical and supercritical flow.

The calibration and validation procedures listed above both utilize a known water surface elevation as a downstream boundary condition within each of the HEC-RAS model. As downstream water elevations are not known for other flow scenarios two methods have been explored to determine downstream boundary conditions.

Headpond Inundation Mapping Hydraulic Report
Frederick House River-Wanatango Falls
June 29, 2011

Firstly, the normal depth boundary condition has been explored. This method assumes a normal laminar flow within a reach and accordingly a numerical river profile slope is entered as a boundary condition. As survey data typically only extends a short distance downstream of the project site and therefore the normal depth slope has been iterated to observe flood water fluctuations in the reach. Given the relatively flat nature of the downstream limits of The Wanatango Falls Site, it has been observed that small fluctuations in the normal depth slope have large impacts on the water surface elevations.

Observing the fluctuations of the downstream computed water surface elevations using a normal depth slope as a boundary condition, an alternative method was further explored. Utilizing HEC-RAS's computational abilities, the critical depth boundary condition was selected.

Using aerial photography and site photos, the Frederick House River was explored and observed downstream of the project limits. The purpose of this exploration has been to determine a location of rapids downstream of the project limits at which it was anticipated that flows would enter a supercritical state.

Downstream of the project limits, flows within the Frederick House River appear to be laminar for a distance of approximately 2.0km. Further beyond the 2.0km threshold, flows enter a supercritical state through a series of rapids. Accordingly, the 2.0km threshold has been used in the HEC-RAS model for further computational purposes.

The most downstream survey cross section (**Survey Section (SS3)**, Burnside Section ID 121) was then copied to a distance of 2.0km downstream. To utilize the iteration capabilities of HEC-RAS, a total of 10 copied cross sections(SS3), spaced at 1m apart, have been further coded into the model at this location. By selecting critical depth as a boundary condition, HEC-RAS will default to a critical depth at the most downstream cross section. HEC-RAS then further performs a series of water surface iterations with the upstream cross sections in search for a normal depth flow condition. By coding a series of cross section is close proximity to one another, it has been observed that normal depth flow conditions are experienced prior to the limits of these copied cross sections. Therefore normal depth flow conditions are also produced back to downstream limits of Wanatango Falls. Additional information supporting the critical depth boundary condition applicability and water surface elevation iteration procedure can be referenced in Chapter 2 of the HEC-RAS Reference Manual ^{IV}.

To determine the validity of this critical depth boundary condition, the computed water surface elevations for the Calibration Flow and Validation flow were then compared to the surveyed and LIDAR water surface elevations respectively. The computed water surface elevations (using the critical depth boundary condition) for both flow scenarios

have produced comparable results ($\pm 0.20\text{m}$) to those produced with a known water surface boundary condition. The LTAF flow was then further explored. It has been noted, in the majority of the project sites that the LTAF flow is greater than the calibration flow, yet less than the validation flow. Computed water surface elevations for the LTAF flow, seem to fit quite well between the calibration and validation water surface elevations, also utilizing the critical depth boundary condition. Therefore, this boundary condition has been employed for all project sites.

The upstream boundary condition was also explored. Surveyed and LIDAR water surface elevations at the upstream limits of each site were observed to be relatively flat and therefore experiencing normal depth flow conditions. For calibration and validation purposes a known water surface elevation was used. For all other flow scenarios the normal depth slope method was used, assuming a relatively flat slope of 0.0001m/m .

Additional commentary discussing the sensitivity of each boundary condition will be outlined in **Section 4.3.3** below.

4.3.2 High Water Mark Methodology

As initially discussed in **Section 2.0** above, the High Water Mark (HWM) peak flow for Wanatango Falls has not been provided. Accordingly, the HWM flow will be determined through a series of modeling iterations. Evidence of the HWM elevations have been provided by BPR Engineering^j and have been identified at each survey section in the field. The HWM elevations have been identified by observing historical flood elevation scaring on rocks, trees, etc. Typically, multiple high water mark elevations have been provided at each survey section.

It has been assumed that a flow range rather than a single flow would be more representative of the high water elevations within each reach. Accordingly, an average surveyed elevation has been used at each cross section for determination of a corresponding flow scenario. Iterating several flows scenarios, a high water mark flow range for Wanatango Falls has been determined to be $55\text{-}160\text{m}^3/\text{s}$. The range of flow scenarios and comparisons between the computer water surface elevations and surveyed elevations have been provided in **Figure 3 in Appendix A**,

4.3.3 Sensitivity Analysis

A sensitivity analysis was completed to determine an effect of varying manning's roughness coefficients, upstream and downstream boundary conditions.

Typical manning's n values as outlined in **Section 4.1** above were varied $\pm 20\%$ of the initial estimated value. Computed water surface elevation fluctuations have been

observed to be $\pm 0.10\text{m}$ for increasing or decreasing roughness coefficients. This fluctuation is minor and has not been assumed to have a significant impact on the computed water surface elevations.

As previously discussed in **Section 4.3.1**, a sensitivity analysis was completed by varying the downstream boundary condition. The normal depth boundary condition has been observed to be quite sensitive to the downstream normal depth slope computations. Accordingly, the critical depth boundary condition has been used for The Wanatango Falls.

The normal depth slope of the upstream boundary condition has been varied $\pm 20\%$ of the initially estimated channel slope. This boundary condition has been observed to have a negligible impact of computed water surface elevations.

4.4 Proposed Conditions

Steady state hydraulic modeling of the proposed structure has built on the existing conditions modeling previously discussed. The proposed structure of each project site has been coded into HEC-RAS geometric data as an Inline Structure. Conceptual drawings the proposed structure has been provided by HATCH Engineeringⁱⁱⁱ. These drawings have been used to identify key dimensions, location and orientation of the proposed structure. Two weir crest elevations of 257.50m and 259.0m have been modeled as directed by Xeneca. Proposed condition results for each weir crest elevation have been illustrated on **Figure 5, in Appendix A**. The column headings starting with “A-PR” (Scenario A) represent proposed flood elevations with a weir crest elevation of 257.50m. Similarly, column headings starting with “B-PR” (Scenario B) represent proposed flood elevations with a weir crest elevation of 259.0m.

Proposed condition flows have been adjusted in the vicinity of the structure in accordance with the configuration of the dam. At the upstream limits of the proposed structure, design flows as provided in by Xeneca have been subtracted from each flow scenario as a portion of flows approaching the structure would be used for producing electricity. Downstream of the proposed structure the design flows have been re-added to each flow scenario at the limits of the spillway

4.5 Existing vs. Proposed Condition Comparison

It has been observed that computed water surface elevation differences between existing and proposed conditions are most noticeable within the head pond area upstream of the structure. Flood elevation increases have been noted to be in the range 0.1-3.5m depending on location. Extents of the head pond area, existing versus proposed comparisons of computed water elevations for the LTAF, 2-year and 100-year flow scenarios illustrated within **Figure 5 in Appendix A**.

Headpond Inundation Mapping Hydraulic Report
Frederick House River-Wanatango Falls
June 29, 2011

Specific attention and observation has been directed to the Inundation Limit of each of the LTAF, 2 and 100-year flow scenarios. For the purpose of this report the Inundation Limit will be defined as the location of reach upstream of the proposed hydroelectric dam where there is a zero water surface elevation difference between the existing and proposed condition flood elevations.

The Inundation Limits for the LTAF, 2 and 100-year flows in Scenario A have been identified to be located between 750-780m upstream of the proposed structure. The Inundation Limits for the LTAF, 2 and 100-year flows in Scenario B have been observed to stretch approximately 9.8km upstream to the base of the Frederick House Dam

HEC-RAS output summaries for existing conditions, proposed Scenario A and Scenario B have been provided in **Appendix B**.

5.0 Un-Steady State Modeling

HEC-RAS has the unique ability to model variations in flow within a standard time step. Often flow hydrographs are used in unsteady state hydraulic models which correspond with hydrologic runoff, typical daily dam operations, dam break analysis, etc. Unsteady state hydraulic modeling has been completed downstream of the proposed structure. The unsteady state model will define flow pulsing characteristics and reflect normal operating conditions. The un-steady state modeling will provide an understanding of flow conditions moving downstream of the proposed structure associated with attenuation of the pulse curve. The proposed unsteady state hydrograph shape, criteria and duration or each site has as been provided by ORTECH (ORTECH) Environmental. The downstream reach length of interest for The Wanatango Falls has been identified by ORTECH to be 2km.

The un-steady state modeling for the Wanatango Falls Site has been completed using previously modeled river geometry downstream of the proposed structure. As, previously outlined in **Sections 4.1 and 4.2**, the steady state models have been calibrated and validated to within 0.3m. Given the variance in channel geometry, flow characterizations and overall profile of the river within the area of interest as identified by ORTECH, the unsteady state modeling has produced un-stable results. It is recommended that additional survey be completed downstream of the proposed structure within the 2.0km area of interest should the results of the unsteady state modeling need to be subject to further analysis.

Frederick House River-Wanatango Falls
June 29, 2011

6.0 Conclusions and Recommendations

The results of the steady, un-steady state modelling and flood line mapping for the Wanatango Falls site outlined in this report has been included within **Appendix A and Appendix B**. Digital modelling files have been provided on a CD and included at the back of this report.

The hydraulic methodology, commentary and results outlined in this report have been based on available information, correspondence and key assumptions made during the course of the project. The results in this hydraulic report have been prepared for the preliminary stages only of determining floodline inundation elevations for each respective site. It is recommended that additional reconnaissance be completed to better define downstream boundary conditions, calibration of additional flows with corresponding surveyed water surface elevations, flow conditions in critical areas, etc.

The modeling, analysis and presentation of hydraulic information have been prepared using the best available information at the time of writing of this report. The results of this report and mapping are to be used in the Environmental Assessment of the proposed hydro-electric dams. Burnside understands that the hydroelectric dam is conceptual at this stage and as such the inundation mapping should be verified as detailed design progresses.

If you have any questions, or require further information, please do not hesitate to contact the undersigned.

High Water Mark Notes

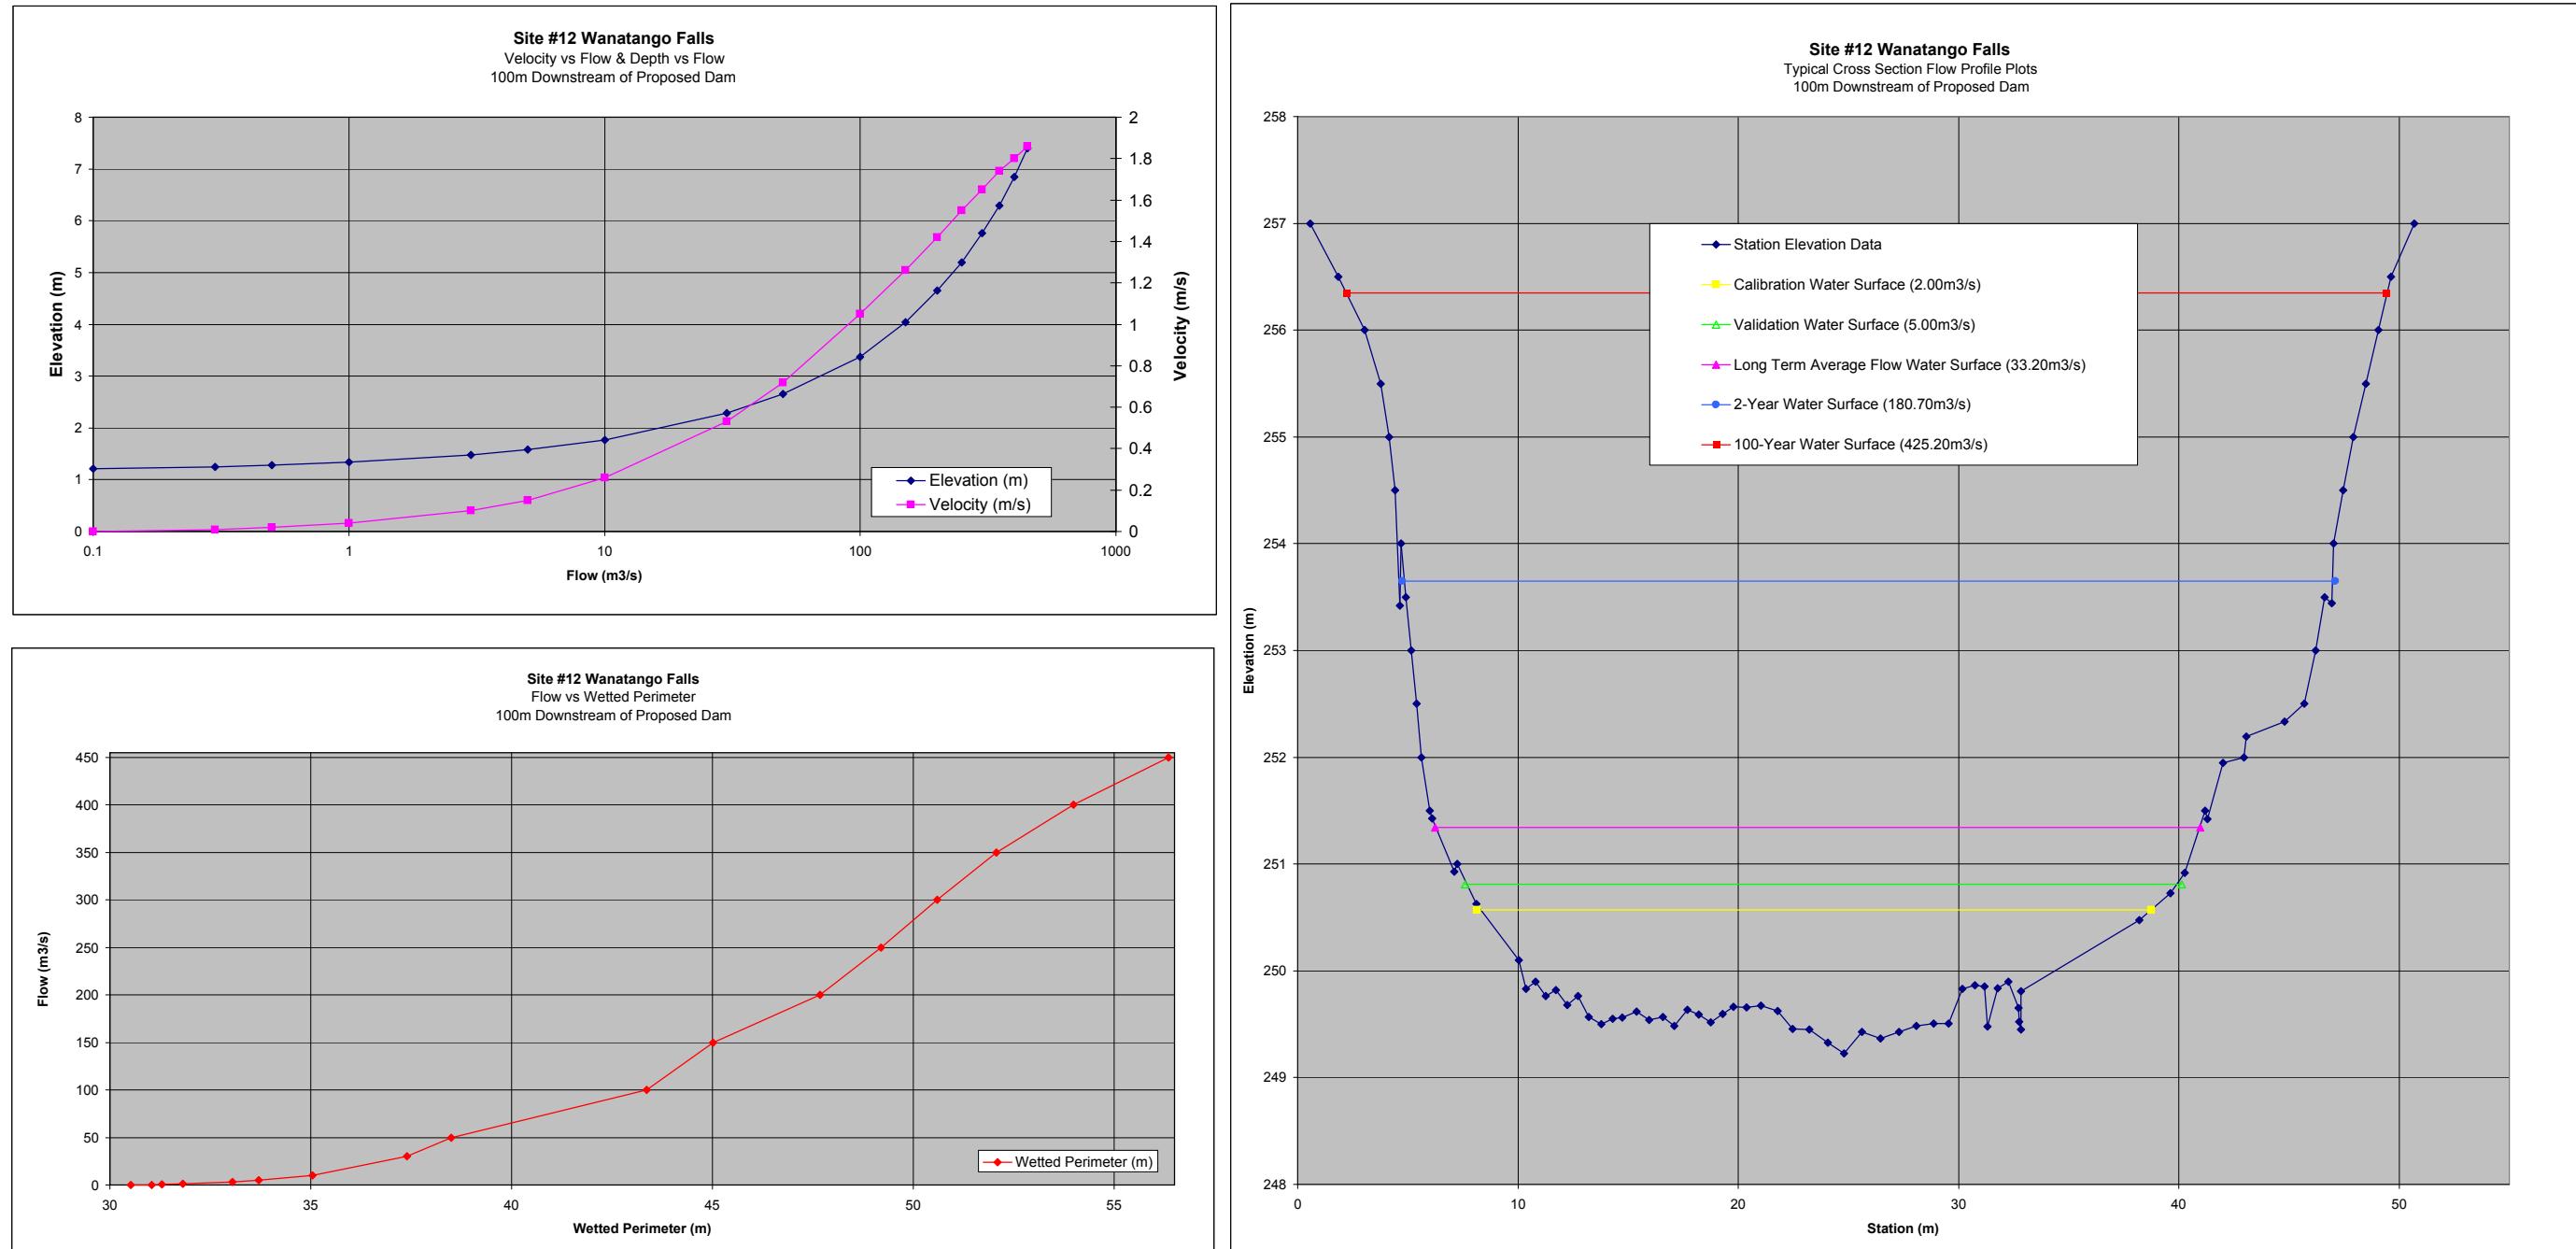

- The High Water Flow Mark range for the Wanatango Falls site has been determined to be 55-160m3/s

Project Name: Xeneca FIT Contract- Headpond Inundation mapping
 Project No.: PCG019617
 Site: 12_Wanatango Falls
 River: Frederick House River
 Designed by: T.Lozon
 Checked by: D.Miller
 Date Created: 28-Jun-11

Figure #4-Site #12 Wanatango Falls - Typical Cross Section Plot

Project Name: Xeneca FIT Contract- Headpond Inundation mapping
 Project No.: PCG019617
 Site: 12_Wanatango Falls
 River: Grand River
 Designed by: T.Loxon
 Checked by: D.Miller
 Date Created: 28-Jun-11

Notes
 -Column headings starting with 'A-PR' represent proposed conditions flood elevations with a weir crest elevation of 257.5
 -Column headings starting with 'B-PR' represent proposed conditions flood elevations with a weir crest elevation of 259.0
